1. Introduction

1. Introduction

—

We aim to present a suite of smart contracts designed to manage NFT auctions using a custom token called SapiCoin.

We used Solidity language for developing this suite of smart contracts.

A Token can be viewed as a class in other programming languages (e.g. Java), however to avoid binding a smart contract to a specific Token we used an abstraction standardized by the Ethereum Community.

In addition to token transfers and auctions, our system includes a liquidity pool implemented using Uniswap v3, which allows users to trade between Ether and SapiCoin.

Design of the standard ERC-20

2.1 ERC-20

2. Tokens

2. Tokens — 2.1 ERC-20

A Model Driven Architecture approach provides a structured method for designing blockchain smart contracts. Using UML diagrams—such as Class and State Machine diagrams—developers can model both the structure and behavioral logic of smart contracts across multiple abstraction layers, improving clarity, analysis, and maintainability.
